## 06 Advanced Regression

**Rahul Bhadani**

**Electrical & Computer Engineering, The University of Alabama in Huntsville**

# Outline

**1. Polynomial Regression**

**2. Locally Weighted Kernel Regression**

**3. Model Diagnostics and Assumption Checking**

# Polynomial Regression

---

# Polynomial Regression

## Regression Model

$$y_i = w_0 + w_1x_i + w_2x_i^2 + \cdots + w_kx_i^k + \epsilon_i \quad (1)$$

In this model, we only have single feature.

# Vectorizing Polynomial Regression

## Regression Model

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^k \\ 1 & x_2 & x_2^2 & \cdots & x_2^k \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & x_n & x_n^2 & \cdots & x_n^k \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ \vdots \\ w_k \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_n \end{bmatrix} \Rightarrow \mathbf{y} = \mathbf{X}\mathbf{w} + \boldsymbol{\epsilon} \quad (2)$$

$\mathbf{X}$  is called the Vandermonde matrix (this is different from  $\mathbf{X}$  obtained in the matrix form of the MLR model).

# Least Square Solution

To find,  $\mathbf{w}$ ,

$$\mathbf{y} = \mathbf{X}\mathbf{w}$$

$$\mathbf{X}^\top \mathbf{X} \mathbf{w} = \mathbf{X}^\top \mathbf{y}$$

Then, the ordinary least square estimate provides the solution as

$$\hat{\mathbf{w}} = (\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top \mathbf{y}.$$

Polynomial regression can be expanded to multiple features.

# Fitted Values and Residuals

The residual term is

$$\mathbf{e}_{n \times 1} = \mathbf{y} - \hat{\mathbf{y}} = \mathbf{y} - \mathbf{X}\hat{\mathbf{w}}$$

The vector of the fitted value  $\hat{\mathbf{y}}$  can be expressed in terms of the hat matrix  $\mathbf{H}$  as

$$\hat{\mathbf{y}}_{n \times 1} = \mathbf{H}\mathbf{y}$$

where

$$\mathbf{H}_{n \times n} = \mathbf{X}(\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top$$

Then, we could also write  $\mathbf{e}_{n \times 1} = (\mathbf{I} - \mathbf{H})\mathbf{Y}$ .

# Polynomial Model with Multiple Features

Polynomial Regression can also expand to multiple features:

$$y_i = w_0 + w_1 \times area + w_2 \times (area)^2 + w_3 \times num\_rooms + w_4 \times yard\_sqft$$

# Locally Weighted Kernel Regression

---

# Intuition

# Intuition

# Intuition

Clearly, here are two sets of data points.

# Intuition

We may benefit from fitting two kinds of regression lines.  
That can be done using a locally-weighted regression line.

# Locally Weighted Kernel Regression

## Implementing Locally Weighted Regression

1. Provide a smoothing parameter  $h$ .
2. Provide a degree of polynomial fit (if you are doing polynomial fit).
3. Select some query points.

# Cost Function for Locally Weight Kernel Regression

## Cost Function

$$J(\mathbf{w}) = \frac{1}{2n}(\mathbf{y} - \mathbf{xw})^\top \boldsymbol{\kappa}(\mathbf{y} - \mathbf{xw})$$

where

$$\boldsymbol{\kappa} = \begin{bmatrix} \kappa_1 & 0 & \cdots & 0 \\ 0 & \kappa_1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \kappa_n \end{bmatrix}$$

is a **kernel function**.

# Estimator

## Closed Form of Estimation

$$\mathbf{w} = \frac{1}{n}(\mathbf{X}\mathbf{K}\mathbf{X})^{-1}\mathbf{X}^{\top}\mathbf{w}\mathbf{y} \quad (3)$$

This method is also called **Lowess** (locally weighted regression scatter plot smoothing) or **Loess**.

# Choosing a Kernel Function

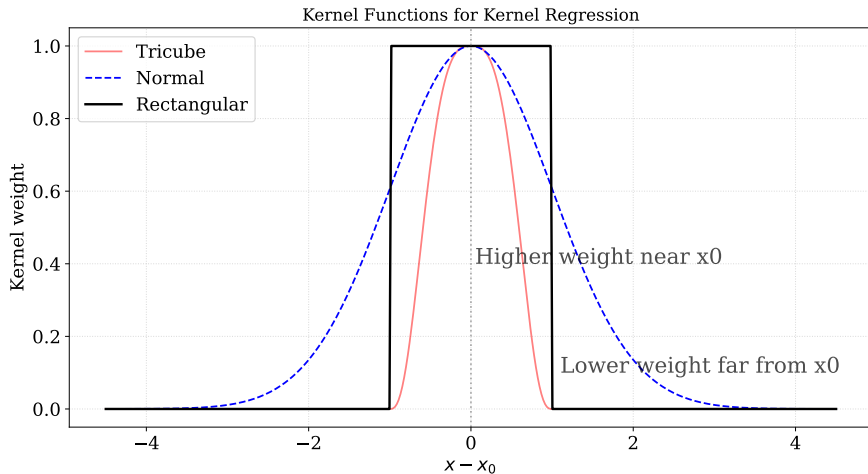

The basic idea of kernel regression is that in estimating the model  $f$ , when we want to fit a regression line in the vicinity of  $x_0$ , it is desirable to give greater weight to observations that are close to the pivot  $x_0$ .

# Choosing a Kernel Function

We first standardize the predictor variable  $x$  as  $z = \frac{x - x_0}{h}$  where  $x_0$  is pivot point, and  $h$  is called kernel bandwidth (which is a design choice).

We need a kernel function  $\kappa(z)$  that attaches greatest weight to observations that are close to the focal  $x_0$  and then falls off symmetrically and smoothly as  $|z|$  grows.

# Some Kernel Functions

# Gaussian Kernel

One popular kernel function for the LWR is Gaussian function (also known as radial basis function (RBF)):

The radial kernel (Radial Basis Function (RBF)) is a Gaussian function, a popular measure of similarity between two data points, and it decreases with the distance ranging from 0 to 1. 1 means two points are identical.

RBF between two points  $x$  and  $x_0$  is defined as

$$\kappa(x, x_0) = \exp\left(-\frac{\|x - x_0\|^2}{2h^2}\right)$$

where  $h$  is the bandwidth of the kernel function.

# The Tricube Kernel

$$\kappa(z) = \begin{cases} (1 - |z|^3)^3 & |z| < 1 \\ 0 & |z| \geq 1 \end{cases}$$

# The Rectangular Kernel

$$\kappa(z) = \begin{cases} 1 & |z| < 1 \\ 0 & |z| \geq 1 \end{cases}$$

# Steps in Implementing Loess

- ⚡ Provide smoothing value,  $h$
- ⚡ Provide degree of  $w$  for the polynomial fit
- ⚡ Select pivot point(s)  $x_0$ .

## Additional Reading and Reference

Chapter 18, Applied Regression Analysis and Generalized Linear Models,  
John Fox, Third Edition, SAGE Publications, Inc.

# Classwork

- ⚡ For Loess, if we choose a different pivot point  $x_0$ , what computation can be reused?
- ⚡ What do we need to store vs what we can compute for a new pivot point?

# Model Diagnostics and Assumption Checking

---

# Assumptions in Linear Regression

1. Linearity
2. Additivity
3. Normality of the Error Terms
4. No Multicollinearity among Predictors
5. No Autocorrelation of the Error Terms
6. Homoscedasticity

# Residual Plot Analysis

- ⚡  $e = \hat{y} - y$  vs  $x$  is called residual plot.
- ⚡ Residual plot provides a valuable information about assumption validation.

# Linearity Assumption in Linear Regression

Simple Linear Regression assumes that there is linear relationship between the predictors (e.g. independent variables or features) and the response variable (e.g. dependent variable or label).

## How to detect the violation of linearity?

- ⚡ Coefficient of Determination
- ⚡ Plot the data 😊

# Additivity Assumption in Linear Regression

Additivity assumes that the impact of different predictors is additive. For example, consider

$$y = w_0 + w_1x_1 + w_2x_2 + \epsilon$$

Additivity says that changing a predictor by some amount will contribute to change in the response in similar proportion.

Example: Let  $\tilde{x}_2 = x_2 + 1$ , then

$$\begin{aligned}\tilde{y} &= w_0 + w_1x_1 + w_2\tilde{x}_2 + \epsilon \\ &= w_0 + w_1x_1 + w_2(x_2 + 1) + \epsilon \\ &= (w_0 + w_1x_1 + w_2x_2 + \epsilon) + w_2 \\ &= y + w_2\end{aligned}$$

Hence, we see incremental change in  $x_2$  causes incremental change in  $y$ .

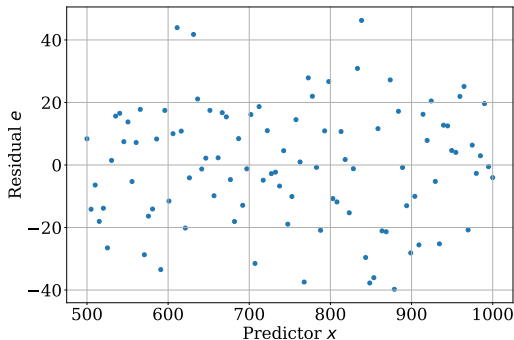

# Additivity Violation

Additivity violation occur when there is interaction term in the true model or a higher order term (e.g.  $x_1x_2$ , or  $x_2^2$ ) that we didn't consider. We can plot correlation matrix to check for additivity violation.

# Normality Assumptions

- ⚡ We assume that error are zero mean constant variance Gaussian distribution.
- ⚡ Scatter plot of residual, and density estimation plot should exhibit any deviation from normality.

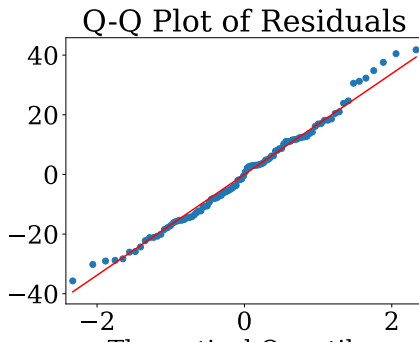

*Follows the normality assumption*

# QQ-plot for Normality

- ⚡ A Q-Q plot (Quantile-Quantile plot) can help in assessing normality assumption.
- ⚡ It compares the quantiles of the residuals from the regression model with the quantiles of a theoretical normal distribution.

*Follows the normality assumption*

# Multicollinearity

- ⚡ In case of multiple regression, if predictor variables are correlated, multicollinearity among them is said to exist.
- ⚡ Plot the scatterplot matrix to check for multicollinearity.

(a) Scatter Plot Matrix of X Variables

(b) Correlation Matrix of X Variables

$$r_{XX} = \begin{bmatrix} 1.0 & .924 & .458 \\ .924 & 1.0 & .085 \\ .458 & .085 & 1.0 \end{bmatrix}$$

$x_1$  and  $x_2$  are highly correlated.

# Autocorrelation

One of the standard assumptions in the regression model is that the error terms  $\epsilon_i$  and  $\epsilon_j$ , associated with the  $i$ th and  $j$ th observations, are uncorrelated.

- ⚡ Correlation in the error terms suggests that there is additional information in the data that has not been exploited in the current model.
- ⚡ When the observations have a natural sequential order, the correlation is referred to as **autocorrelation**. One example may be that the data is a timeseries data.
- ⚡ Or, Adjacent residuals tend to be similar in both temporal and spatial dimensions.

## *Residual Histogram not Gaussian*

# Homoscedasticity and Heteroscedasticity

The equal variance assumption is called **Homoscedasticity**. It means constant variance of residuals across values of each predictor; in other words, residuals are evenly distributed throughout the regression line.

On the other hand

The condition of the error variance not being constant over all cases is called **Heteroscedasticity**.

# Heteroscedasticity in Data

Heteroscedasticity is inherent when the response in regression analysis follows a distribution in which the variance is functionally related to the mean.

# Heteroscedasticity in Data

Heteroscedasticity is inherent when the response in regression analysis follows a distribution in which the variance is functionally related to the mean.

What probability distribution has variance as a function of mean?

# Heteroscedasticity in Data

Heteroscedasticity is inherent when the response in regression analysis follows a distribution in which the variance is functionally related to the mean.

What probability distribution has variance as a function of mean?  
Answer: Poisson distribution.

# Deviation from Homoscedasticity

If a dataset exhibits Homoscedasticity, the scatterplot of the residuals shows a notable uniformity along the horizontal axis.

# Remedial Measures

- ⚡ Lack of Linearity: Use nonlinear regression
- ⚡ Nonconstancy of Error Variance (Heteroscedasticity): Use weighted least square method (or Loess), sometimes transformation are effective too.
- ⚡ Nonindependence of Error Terms: Autocorrelation may be present. Use transformed variables such as  $y(t)_{tr} = y(t) - \rho y(t-1)$
- ⚡ Nonnormality of Error Terms: Transform data. E.g.  $y_{tr} = \sqrt{y}$ ,  $x = \log(x)$ , etc.
